Jordan Real Estate

Data Sources

A Reference Guide to Official, Market, and Unofficial Sources

Internal Research Document | 2026

Overview

This document catalogues the data sources available for real estate market intelligence in Jordan. Sources are organized into three categories: official government sources, market and portal sources, and spatial and secondary sources. For each source, the document covers the data it provides, the level of granularity, how to extract the data, and the key limitations to be aware of.

The central finding across all sources is that Jordan's official data infrastructure provides market-level signals - volumes, indices, and permit counts - but does not release unit-level transaction prices publicly. The granularity gap at the neighborhood and product level is filled primarily by portal data and broker intelligence, which form the foundation of any near-term pricing intelligence system.

> *Sources are assessed as they stand today. The data landscape in Jordan is evolving - DLS has recently launched a new digital platform and is reportedly working on a smart data initiative. It is recommended to revisit this assessment annually.*

A. Official Government Sources

A1. Department of Lands and Survey (DLS)

Source Name	**Department of Lands and Survey - دائرة الأراضي والمساحة**
Links	**Main website:** https://www.dls.gov.jo/Default/En **E-services portal:** https://eservices.dls.gov.jo **Annual reports:** https://www.dls.gov.jo/EN/List/Annual_Reports **Monthly Reports:** **https://www.dls.gov.jo/AR/List/مؤشرات_عقارية** **Plot inquiry (by coordinates):** https://www.dls.gov.jo/Default/En - available from homepage map tool
Data & Granularity	**What is published:** • Monthly real estate trading reports: total transaction volume (JD) and transaction count by governorate, property type (apartment, land, commercial), and nationality of buyer (Jordanian vs non-Jordanian) • Annual statistical yearbooks with multi-year breakdowns of the same metrics • Cadastral maps: freely accessible online for all registered plots across Jordan • Ownership and encumbrance inquiry: status of a specific plot by plot number or GPS coordinates (available to registered users) • Property valuation records: the administrative value DLS assigns to properties for tax and fee calculation purposes **Granularity level:** Governorate level for published statistics. No neighborhood-level or unit-level breakdown is publicly available. Transaction prices at the individual deal level are confidential under Jordanian law and not published.

Extraction Method	• Monthly PDF reports: download manually from the DLS website. Published in Arabic - require translation for systematic use. Recommend assigning a team member to download and log data monthly into a structured spreadsheet. • Annual reports: direct PDF download. More structured than monthly reports; useful for year-over-year trend analysis. • Cadastral maps: accessible online through the DLS map interface. Can be cross-referenced with plot numbers from any transaction record. • Plot inquiry: requires creating a registered account on the e-services portal. Inquiries are per-plot; there is no bulk export. Useful for due diligence on specific acquisition targets, not for market-wide data collection. • Formal data request: Jordan's Access to Information Law No. 47 (amended 2024) gives any party with a lawful interest the right to formally request government data within 30 days. A written request for anonymized aggregate transaction data at the neighborhood level - without personal identifiers or plot numbers - has legal basis and is worth attempting. Submit to DLS Director General's office in writing.
Limitations / Challenges	• No unit-level transaction prices are published. The published data tells you how much traded in total, not what individual properties sold for. • Governorate-level only - no district or neighborhood breakdown in published reports. • Reports are published in Arabic. Consistent extraction requires either Arabic-language capability or a translation workflow. • No API or bulk download mechanism exists. All extraction is manual. • Administrative value (used for fee calculation) is not the same as market value and should not be used as a price proxy. • The formal data request route under the Access to Information Law is untested for real estate data specifically. Implementation across government agencies is inconsistent and requests are sometimes ignored without formal consequences.

A2. Central Bank of Jordan (CBJ) - Real Estate Price Index

Source Name	**Central Bank of Jordan - Real Estate Price Index**
Links	**Price index page 'last updated 2021':** https://www.cbj.gov.jo/En/List/Jordan_Real_Estate_Price_Index **Statistical database:** http://statisticaldb.cbj.gov.jo/index?lang=en **Monthly statistical bulletin:** https://www.cbj.gov.jo/En/List/Monthly_Statistical_Bulletin
Data & Granularity	**What is published:** • Quarterly Real Estate Price Index: tracks price change for apartments, houses, villas, and residential land. Base year is 2012. Produced jointly with DLS using actual registered transaction data. • Breakdown available by: property type (4 categories) and by governorate. • Monthly statistical bulletins: include real estate trading volumes and banking sector credit exposure to real estate and construction.

	• Historical data available from 2012 to present - the longest continuous price series available for Jordan. **Granularity level:** Governorate level. No neighborhood breakdown. The index measures price direction and magnitude - it does not give absolute prices per square meter. It is a change measure, not a value measure.
Extraction Method	• Index tables: published as Excel files and PDFs on the CBJ price index page. Direct download, no login required. Updated quarterly - typically released 6 to 8 weeks after quarter end. • Statistical database: browse and export tables at statisticaldb.cbj.gov.jo. Allows filtering by indicator and time period with Excel export. No API. • Recommended workflow: download the index quarterly, maintain a running spreadsheet tracking the index value for each governorate and property type, and use it to calculate time-adjustment factors for comparable sales data.
Limitations / Challenges	• Measures price change, not absolute price levels. Cannot be used directly to say 'apartments in Amman cost X JD/m²'. • Governorate level only - cannot distinguish Abdoun from Zarqa within Amman governorate. • Quarterly frequency means it lags the market by up to 3 months, plus the publication delay. • Index methodology (Laspeyres with 2012 base) means it can become increasingly unrepresentative of the current market as the composition of properties traded shifts significantly from the base year basket. • No API. Extraction is manual.

A3. Department of Statistics (DoS)

Source Name	**Department of Statistics - دائرة الإحصاءات العامة**
Links	**Main website:** https://dosweb.dos.gov.jo **Building permits:** https://dosweb.dos.gov.jo/industry/building-licenses/ **Jordan Data Portal:** http://jdp.dos.gov.jo
Data & Granularity	**What is published:** • Monthly building permits: number of licenses issued, total licensed area in m², broken down by governorate, occupancy type (residential, commercial, industrial), and construction material. • Quarterly construction activity data: value of work underway, by sector and governorate. • Population and housing census: household size, dwelling type, ownership vs rental rates, housing unit counts by area. Most recent census 2015; new census results anticipated. • Consumer Price Index: includes a shelter component tracking rental price movements at the national level.

	Granularity level: Governorate level for most data. Building permits data is the most relevant for real estate market analysis - it provides the only systematic forward-looking supply indicator available from an official source.
Extraction Method	• Building permits: monthly PDF reports downloadable from the DoS website. Some data also available via the Jordan Data Portal with limited export functionality. • Census data: available as published reports and selected tables on the DoS website. • For microdata beyond published aggregates: submit a formal written request to DoS via Customer.Service@DOS.GOV.JO. Microdata access requires an institutional justification and is not guaranteed.
Limitations / Challenges	• Building permits measure licensed area - not actual construction starts or completions. A permit does not mean a building gets built; many permits in Jordan are issued but construction is delayed or cancelled. • Governorate level only - no district or neighborhood breakdown for supply pipeline analysis. • Census data is now a decade old and increasingly unreliable for demographic inputs into demand models. • The shelter component of the CPI is a national aggregate and too broad to be useful for neighborhood-level rental analysis. • No API. All extraction is manual PDF download.

B. Spatial and Municipal Sources

B1. Greater Amman Municipality (GAM) - GIS and Planning Data

Source Name	**Greater Amman Municipality - أمانة عمان الكبرى**
Links	**GIS portal:** https://www.ammancitygis.gov.jo **ArcGIS REST API:** https://www.ammancitygis.gov.jo/arcgis/rest/services **Urban Observatory:** https://media.ammancity.gov.jo/En/List/Amman_Urban_Observatory **E-services:** https://e-services.ammancity.gov.jo **Planning documents:** https://media.ammancity.gov.jo/EN/Pages/About_the_Municipality
Data & Granularity	**What is available:** • Zoning classifications by plot: Residential A, B, C, D, Commercial, Industrial, Agricultural - the regulatory layer that defines permitted floor area ratios, maximum heights, setbacks, and permitted uses. This is the single most valuable spatial dataset for real estate analysis in Jordan. • Neighbourhood and district boundaries: administrative polygons for all of Amman's districts. • Street network and road classifications. • Points of interest: schools, hospitals, commercial facilities, mosques, public spaces. • Urban Observatory indicators: population density, land cover, infrastructure quality, housing conditions at district level. Published periodically, not in real time. • Master plan documents: development corridor designations, planned infrastructure investments, land use future projections. **Granularity level:** Plot level for GIS zoning data - the finest granularity of any official source. Amman only; no equivalent exists for other Jordanian cities.
Extraction Method	• GIS portal: interactive web map accessible at ammancitygis.gov.jo. Individual plot queries can be made visually. • ArcGIS REST API: the most technically valuable extraction route. The public ArcGIS endpoint allows programmatic queries using Python's arcgis library or direct HTTP requests, returning data in GeoJSON or shapefile format. The zoning layer can be downloaded and joined to a property transaction database to automatically assign zone classifications to each deal. This is a significant analytical capability that requires a one-time technical setup but provides ongoing value. • Urban Observatory reports: PDF downloads from the GAM media site. • Master plan documents: available as PDFs in Arabic on the GAM website. Require translation and manual interpretation.

Limitations / Challenges	• Amman only. No equivalent GIS platform exists for Irbid, Zarqa, Aqaba, or any other Jordanian city. This limits the approach to projects within Amman's municipal boundary. • Zoning data reflects current designations, which can change. Master plan amendments require monitoring. • ArcGIS API requires technical capability to query and process. Not a point-and-click data source. • Urban Observatory data is published irregularly and may be up to 2 to 3 years old. • Building permit data at the plot level is not publicly accessible - GAM does not publish permit microdata, only DoS aggregates.

B2. Other Municipalities and OpenStreetMap

Source Name	**Municipal data outside Amman + OpenStreetMap**
Links	**OpenStreetMap Jordan extract:** https://download.geofabrik.de/asia/jordan.html - updated daily, free download **ASEZA (Aqaba):** https://invest.jo/investment-zones/aqaba/ **Jordan Open Data Portal:** https://www.opendata.gov.jo
Data & Granularity	**What is available:** • OpenStreetMap Jordan: road networks, building footprints, land use polygons (residential, commercial, industrial, agricultural), points of interest - for all cities and towns across Jordan. Updated daily by community contributors. Available as shapefile or GeoPackage. • ASEZA Aqaba: land use master plan with defined zoning categories (tourism, logistics, industrial). Available as PDF planning documents, not a live GIS feed. • Jordan Open Data Portal: minimal real estate content. Other ministries contribute some datasets but none of direct pricing relevance. **Granularity level:** OpenStreetMap provides physical geography at street and building level. It does not include regulatory zoning classifications, building heights, permitted uses, or any transaction data. Coverage quality varies - urban Amman and major cities are well-mapped; smaller towns are sparser.
Extraction Method	• OpenStreetMap: download the Jordan extract from Geofabrik as a shapefile or GeoPackage. Import into QGIS or any GIS tool. Free, no registration required. Can be joined to property databases using coordinate matching. • ASEZA: contact their investor relations office directly for planning documentation. • Other municipalities: plot-level zoning information must be obtained by visiting the relevant municipal engineering department in person and requesting it for a specific plot. No digital alternative exists.
Limitations / Challenges	• OSM does not contain zoning classifications - the most valuable regulatory attribute for pricing. It shows what physically exists, not what is permitted.

[redacted]	• OSM data quality is community-dependent. Completeness and accuracy varies significantly between areas and requires validation before use in analysis. • No single source provides GAM-equivalent spatial intelligence for cities outside Amman. For projects in Irbid, Zarqa, or elsewhere, zoning data must be obtained manually on a plot-by-plot basis from the relevant municipality.

C. Market and Portal Sources

C1. Bayut Jordan

Source Name	**Bayut Jordan - bayut.jo**
Links	**Main portal:** https://www.bayut.jo/en/ **Sale listings:** https://www.bayut.jo/en/jordan/properties-for-sale/ **Rental listings:** https://www.bayut.jo/en/jordan/properties-for-rent/
Data & Granularity	**What is available:** • Active property listings: asking price, size in m², bedrooms, bathrooms, floor level, furnishing status, parking, building age, area and neighborhood, listing date, listing ID, agent or developer name, property photos. • Covers both sale and rental markets across Jordan, with highest density in Amman. • Listing history: by tracking listing IDs over time, it is possible to observe price reductions, time on market, and eventual removal (proxy for sale or withdrawal). **Granularity level:** Neighborhood and building level for active listings. The most granular market data available from any source. Prices are asking prices, not transaction prices - a systematic gap of approximately 5 to 15% exists in the Jordanian market.
Extraction Method	• No official API or bulk export. Data must be scraped. • Technical approach: the site uses JavaScript rendering, so a headless browser (Playwright or Selenium) is required to load listings fully before extraction. Standard HTTP requests alone will not retrieve listing data. • Tools: Python with Playwright is the recommended stack. Apify also offers a pre-built Bayut scraper that can be configured without writing custom code - suitable if in-house technical capability is limited. • Recommended workflow: run a scrape monthly covering the target submarkets (Abdoun, Khalda, Sweifieh, Dabouq, and others relevant to active projects). Store each listing with a timestamp and listing ID. Compare month-over-month to identify: new listings (new competition), removed listings (sold or withdrawn), and price changes on existing listings. • Use rotating proxies and rate-limited requests to avoid detection. Respect reasonable crawl delays.
Limitations / Challenges	• Asking prices only - not transaction prices. All price-per-m² figures derived from Bayut must be discounted by a market-calibrated factor (broker intelligence is the source for this adjustment). • Listing quality varies. Private seller listings often have incomplete or inaccurate attribute data. Agent listings are generally more reliable. • No way to confirm whether a removed listing sold (vs. withdrawn). Broker intelligence is needed to distinguish between the two.

	• Scraping requires ongoing technical maintenance as the site structure changes. If the site updates its rendering or anti-scraping measures, the scraper needs updating. • Terms of service do not permit scraping. Risk is low for internal research purposes but should be noted.

C2. OpenSooq Jordan

Source Name	**OpenSooq Jordan - jo.opensooq.com**
Links	**All real estate:** https://jo.opensooq.com/en/real-estate **Sale listings:** https://jo.opensooq.com/en/real-estate-for-sale **Rental listings:** https://jo.opensooq.com/en/real-estate-for-rent
Data & Granularity	**What is available:** • General classifieds-style listings covering apartments, villas, land, and commercial properties. Higher volume than Bayut but lower average data quality per listing. • Fields available: price, size, area, floor, furnishing, and seller type (individual vs. agent). • Strong presence for private seller listings - complements Bayut's predominantly agent-sourced inventory. **Granularity level:** Neighbourhood level. Data is less structured than Bayut - more free-text, fewer standardised fields. Requires a cleaning step before analytical use.
Extraction Method	• No API. Scraping required using the same approach as Bayut - headless browser needed for JavaScript-rendered content. • Listings load dynamically on scroll (infinite scroll pagination), so the scraper must simulate scrolling or use pagination parameters to capture all results. • Recommended to run in parallel with Bayut scraping on the same monthly cycle. OpenSooq captures segments of the market (private sellers, lower price points) that Bayut may underrepresent.
Limitations / Challenges	• Lower data quality than Bayut. Many listings have missing or inconsistent attribute fields requiring manual review or NLP-based extraction. • Higher proportion of private seller listings means more noise - price expectations from private sellers are often less calibrated to market reality than agent listings. • Same limitations as Bayut: asking prices only, scraping required, no confirmation of transaction outcomes.

C3. Homes Jordan

Source Name	**Homes Jordan - homes-jordan.com**
Links	**Sale listings:** https://www.homes-jordan.com/en/property/sale **Rental listings:** https://www.homes-jordan.com/en/property/rent **Market blog:** https://www.homes-jordan.com/en/blogs
Data & Granularity	**What is available:** • Curated listings focused on mid-to-upper market residential in Amman - primarily Abdoun, Dabouq, Khalda, Sweifieh, and Shmeisani. Listing data includes price, size, detailed attribute descriptions, and verified agent contacts. • Market blog: monthly posts summarising DLS transaction data and market commentary. Useful as a translated, summarised version of official DLS data without navigating Arabic-language government sites directly. **Granularity level:** Neighbourhood level. Smaller volume than Bayut or OpenSooq but higher data quality and more relevant for premium residential segments.
Extraction Method	• Smaller inventory makes manual monitoring feasible alongside any scraping operation. A monthly review of active listings in target neighbourhoods can be done without technical tooling. • Blog posts on DLS data: monitor and download monthly as a secondary verification of official DLS figures.
Limitations / Challenges	• Limited to upper-market Amman segments - not representative of broader Jordan or mid-market products. • Same asking-price limitation as all portals. • Lower listing volume means limited statistical value for regression or benchmarking - more useful for qualitative market intelligence and individual comparable lookup.

D. Social and Community Sources

D1. Facebook Public Groups

Source Name	**Facebook Public Real Estate Groups - Jordan**
Links	No fixed URLs - groups are searched within Facebook. Key search terms: عقارات الأردن / أراضي للبيع/ شقق للبيع عمان/ عقارات عمان
Data & Granularity	**What is available:** • Listings posted by agents, developers, and private sellers in active public groups. Posts typically include asking price, area in m², number of rooms, district or neighborhood, floor, and contact information. • Market sentiment signals: comments and reactions on listings indicate level of interest. High engagement on a listing type can signal demand. • Developer and project announcements: new launches, payment plan structures, incentive offers. • Informal price intelligence: agents sometimes post sold prices or mention achieved prices in comments. **Granularity level:** Neighborhood level where stated. Data is unstructured - prices and attributes are embedded in free Arabic text and require extraction before analysis.
Extraction Method	• Public group content is accessible without authentication and is legally scrapable under most frameworks (publicly available data principle confirmed by major court rulings including hiQ Labs v. LinkedIn 2022). • Facebook Graph API: provides access to some public group content within defined rate limits. Most legally straightforward approach. • Third-party tools: Apify and PhantomBuster offer Facebook group scraping functionality. Apify is recommended for teams with some technical capability; PhantomBuster for less technical users. • Text extraction: posts are in Arabic free text. A lightweight NLP pipeline or AI-assisted extraction step is required to parse price, size, area, and other attributes from post content. This adds complexity but is manageable. • Recommended cadence: weekly monitoring of the 5 to 10 most active groups relevant to target submarkets.
Limitations / Challenges	• All prices are asking prices from an even less curated source than portals. Private sellers in Facebook groups tend to have the most optimistic pricing expectations. • Arabic free text requires NLP processing to extract structured data. Post quality and completeness varies widely. • Facebook regularly changes its platform structure and API access policies. Scrapers require maintenance. • Private groups, direct messages, and any content behind authentication walls cannot be accessed. The most exclusive and highest-value market information often circulates in private channels.

D2. WhatsApp Broadcast Networks

Source Name	**WhatsApp Broker and Developer Networks**
Links	Not applicable - access is by invitation only through broker and industry relationships.
Data & Granularity	**What is available:** • In Jordan's market, WhatsApp is the primary channel for real-time deal flow. Active brokers operate broadcast groups sharing new listings, price reductions, and sold notifications before they appear on any portal. • Developer teams use WhatsApp to share payment plans, launch prices, and reservation availability with their broker networks - often ahead of any public announcement. • Achieved transaction prices are sometimes shared informally in broker groups - the closest available source to real transaction intelligence outside the DLS. **Granularity level:** Deal level in some cases. Highly valuable but entirely informal and non-systematic.
Extraction Method	• Cannot be scraped or accessed programmatically. WhatsApp end-to-end encryption and closed group structure makes automated collection technically impossible and legally impermissible. • The only extraction method is human intelligence: building relationships with 5 to 10 active brokers in each target submarket, joining their broadcast groups, and assigning a team member to monitor and log relevant price signals on a weekly basis. • Structure this as a monthly 'broker survey': a short structured conversation or WhatsApp message to each broker contact asking specific questions - what has transacted recently, at what price, how long did it take to sell, what are buyers asking for. Logged answers become a proprietary dataset over time.
Limitations / Challenges	• Entirely relationship-dependent. Quality of intelligence is proportional to quality of broker network. • Not systematic and not reproducible. Two people building broker networks will capture different information. • Information shared informally may be inaccurate - brokers have incentives to shape market perception. Cross-referencing across multiple contacts is essential. • No ability to scale or automate. Always a human intelligence function.

E. Summary Assessment

The table below summarizes all sources by category, data type, granularity, and whether the extraction is automated, manual, or relationship-based.

Source	Category	Data Type	Granularity	Cost	Extraction
DLS	Official	Volumes + cadastral	Governorate	Free	Manual PDF
CBJ Index	Official	Price index (change)	Governorate	Free	Manual Excel
DoS	Official	Permits + census	Governorate	Free	Manual PDF
GAM GIS	Spatial	Zoning + land use	Plot level	Free	API / manual
OpenStreetMap	Spatial	Physical geography	Street level	Free	Bulk download
Bayut	Portal	Asking prices	Building level	Free*	Scraping
OpenSooq	Portal	Asking prices	Neighborhood	Free*	Scraping
Homes Jordan	Portal	Asking prices	Neighborhood	Free*	Manual / scrape
Facebook Groups	Social	Asking prices	Neighborhood	Free*	Scraping
WhatsApp Networks	Social	Deal intelligence	Deal level	Free*	Human only

* Free to access publicly; scraping may conflict with platform terms of service.

Key Observations

- No source in Jordan provides publicly accessible unit-level transaction prices. This is the fundamental data gap that all market intelligence approaches must work around.
- Official sources (DLS, CBJ, DoS) provide reliable macro signals at governorate level but offer no neighborhood or product-level granularity. They are essential for market context and trend direction but insufficient for pricing decisions on their own.
- GAM GIS is the only official source with plot-level spatial granularity, and it covers Amman only. Its zoning layer is a genuinely underexploited asset for developers - integrating it with a transaction database via the ArcGIS API would provide automatic zone classification for every deal.
- Portal data (Bayut, OpenSooq) is the primary source for neighborhood and product-level price benchmarking. It provides asking prices, not transaction prices. The asking-to-transaction gap must be calibrated through broker intelligence.
- Broker networks and WhatsApp intelligence are the only routes to real transaction-price data in practice. This information is informal, relationship-dependent, and non-systematic - but it is the closest available proxy to what the DLS knows but does not release.
- Social media (Facebook groups) adds volume and informality to the asking-price picture and captures market segments - private sellers, lower price points - that portals may underrepresent. WhatsApp cannot be automated and requires a human intelligence function.
